Module 5 Assignment 5A:
Designing Your Own Object Oriented World

Course: CS 85 - PHP Programming
Instructor: Vicky Seno

For this assignment, I created an interactive PHP page that demonstrates Object-Oriented Programming using a real-world topic from my life and work as a photographer. I designed a PhotographyBooking class based on my SERGIOARTG photography platform https://sergioartg.com , where clients can request portrait or fashion sessions, receive pricing quotes, pay deposits, and move through a booking workflow.

The class includes multiple properties such as photographer name, brand name, client name, service type, package name, price, duration, retouched photos, shoot date, location type, booking status, deposit amount, rush delivery, and notes. I added a constructor to initialize each booking object with realistic data.

The page creates two booking objects and lets the user interact with class methods directly through the UI. The buttons run methods that display a booking summary, calculate the total quote, calculate the deposit due, add extra retouched photos, record a deposit payment, change the booking status, and run decision logic for booking priority and confirmation.

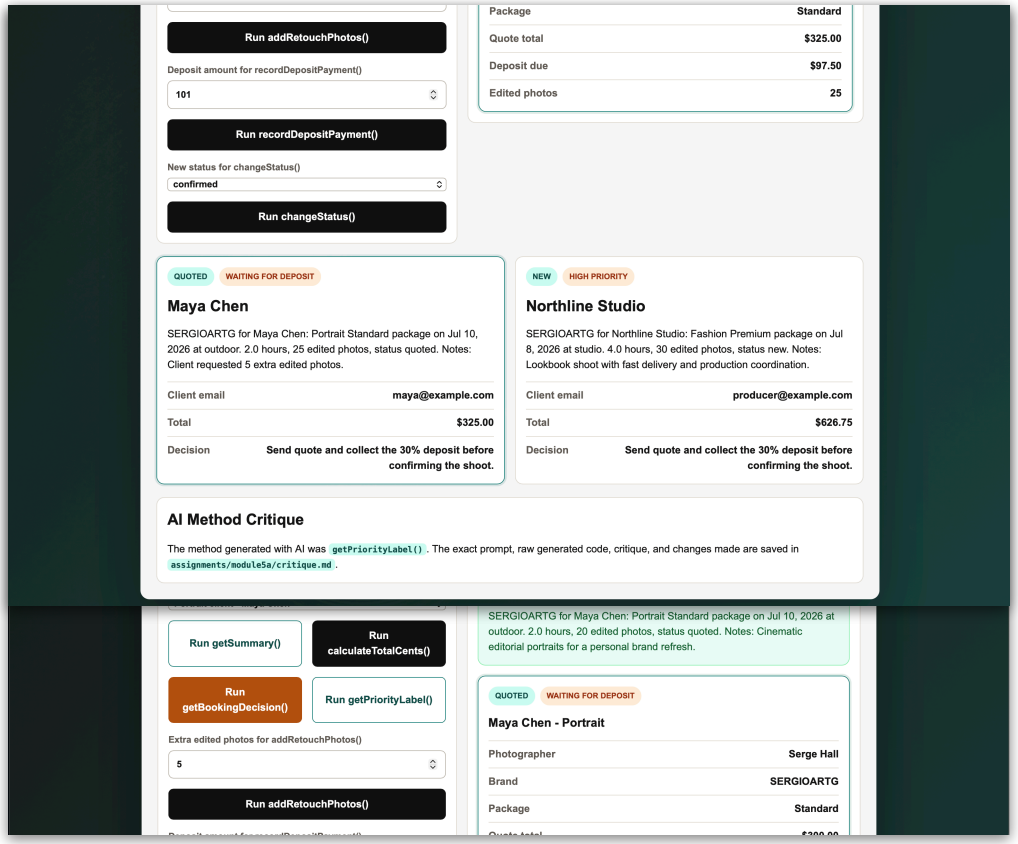

I also used AI to generate one method, then included the exact prompt, raw AI-generated code, and a critique explaining security, efficiency, correctness, style, and the changes I made.

```
# Module 5 Assignment 5A AI Method Critique
## Method Generated With AI

## Exact Prompt

Write a beginner-friendly PHP class method named getPriorityLabel for a photography booking object. The object has
properties named status, rushDelivery, shootDate, and a method named calculateDepositDueCents(). Return Done when
the booking status is completed, High priority when the shoot is within two days or rush delivery is true, Waiting
for deposit when a deposit is still due, and Normal priority otherwise.

## Raw AI-Generated Code

```php
public function getPriorityLabel() {
    if ($this->status == "completed") {
        return "Done";
    }

    $today = new DateTime();
    $shoot = new DateTime($this->shootDate);
    $days = $today->diff($shoot)->days;

    if ($days <= 2 || $this->rushDelivery == true) {
        return "High priority";
    }

    if ($this->calculateDepositDueCents() > 0) {
        return "Waiting for deposit";
    }

    return "Normal priority";
}
```

Critique

Security: The raw method does not run SQL or print unescaped client input, so the direct security risk is low. The
final page still escapes all rendered output with `htmlspecialchars()` because client names, notes, and booking
details could become user-controlled in a real app.

Efficiency: The method is efficient. It only checks status, date distance, rush delivery, and deposit due. There
is no loop or database call.
```
